## From 'Bandits' to 'Fair Federated Contextual Bandits'

Bandit Problem : Pick the worker with most merit every round

Contextual Bandits : Merit is dependent on the context, $X_t$, observed (ex. Task category)

Federated Learning : Agents working with same/similar workers can learn faster
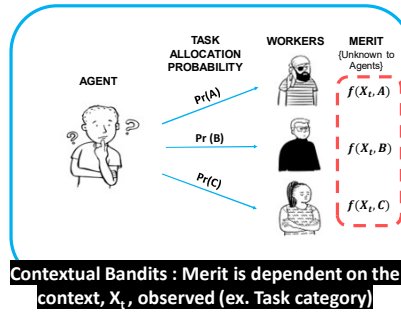

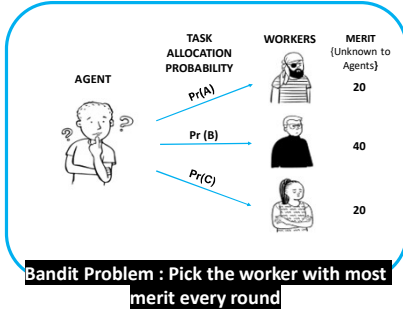

**Fairness of exposure:**
The selection probability ratio of two arms should be equal to merit ratio of the two arms (here workers).

'To be greedy and loose workers to starvation' or 'To be fair and allocate proportional to merit'
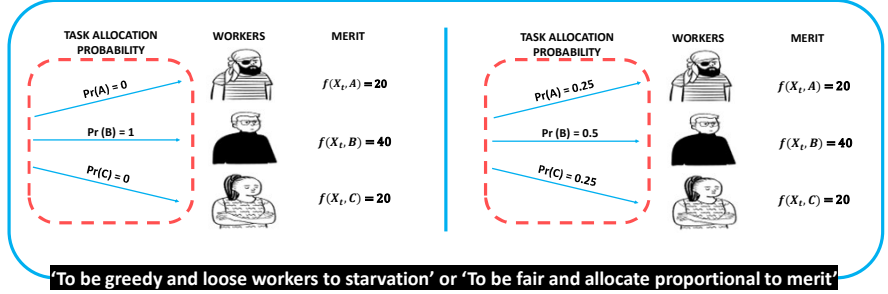

**Goal:** To minimizes fairness regret for federated contextual bandits. Fairness regret is given by the difference norm between chosen and optimal (if merit wasn't unknown) selection probability vectors.

## Differential Privacy

Given that to engage in federated learning, agents have to share their observations (both context and reward), privacy concerns are expected to arise

We have privacy concerns about sharing our observations

**Privacy guarantees should be provided. Specifically, we ensure that our algorithm can provide differential privacy.**

## Communication Protocol

**Phase 1**
Gap doubles between communication rounds every time

**Phase 2**
Periodic communication with fixed bounded gaps

**Bounded number of communication rounds and bounded gaps between any two communication rounds**

## Experimental Results

**B0 – Single Agent Learning**
**B1 – Priv-FairX-LinUCB with Dubey et al 's [1] communication protocol**
**B2 – Priv-FairX-LinUCB with Solanki et al 's [2] communication protocol**

## Theoretical Results

### Fed-FairX-LinUCB (Non-private communication)

**Idea:** Use a novel communication protocol to periodically share observations. Find the optimal selection vector by constructing a confidence region around current estimate using shared gram matrices and reward vectors.

**Theorem 1 (simplified) :** With high probability, Fed-FairX—LinUCB achieves following fairness regret if the context norm is bounded by 1,

$$O\left(\frac{\sqrt{\beta_T}}{\gamma}\sqrt{mTd\log\left(1+\frac{T}{d}\right)+m^2d^3\log^3\left(1+\frac{T}{d}\right)}\right)$$

### Priv-FairX-LinUCB (Private communication)

**Idea:** Use privatizer routine (tree-based mechanism), to calculate noisy gram matrix and reward vectors, before sharing observations.

**Theorem 2 (simplified) :** With high probability, Priv-FairX—LinUCB achieves following fairness regret,

$$O\left(\frac{\sqrt{\beta_T}}{\gamma}\sqrt{mTd\log\left(\frac{\bar{\rho}}{\underline{\rho}}+\frac{T}{d\underline{\rho}}\right)+m^2d^3\log^3\left(\frac{\bar{\rho}}{\underline{\rho}}+\frac{T}{d\underline{\rho}}\right)}\right)$$
